

SEASONAL GRAZING

Seasonal grazing is a great technique that only operating in a specific portion during certain seasons of the whole year. Seasonal grazing also can be combined using rotational and continuous grazing that takes place in that season. By applying this technique, it enables to shorten that time consumption spending on the farming infrastructure and livestock managing.

Different season
conditions provide
different use of
land for certain
species.

FOUR SEASONS

SPRING

Not the most appropriate time for effective grazing. Grazing heavily during spring may decrease the diversity. It is better to keep relatively light grazing in regards to other seasons of the year.

SUMMER

Still not the best time! Light grazing is a more ideal option that intensive grazing in this season can largely destroy the plant saplings and seedlings.

AUTUMN

The best time of the year has come. If you have not approached heavy grazing in spring or summer, the autumn biomass will be its best condition that can maximise its potential for effective grazing.

WINTER

Winter is a chance that you can adjust your whole year grazing regime. A heavy grain in this season is not appropriate that significant grassland disturbance can be found that it is better to let the grass seeds finding their suitable niches for germination in the coming seasons.
